

# Bahrain Airport Company is revolutionizing the Airports Resource Allocation by using predictions calculated using an Event-Driven Architecture (Takhatta)

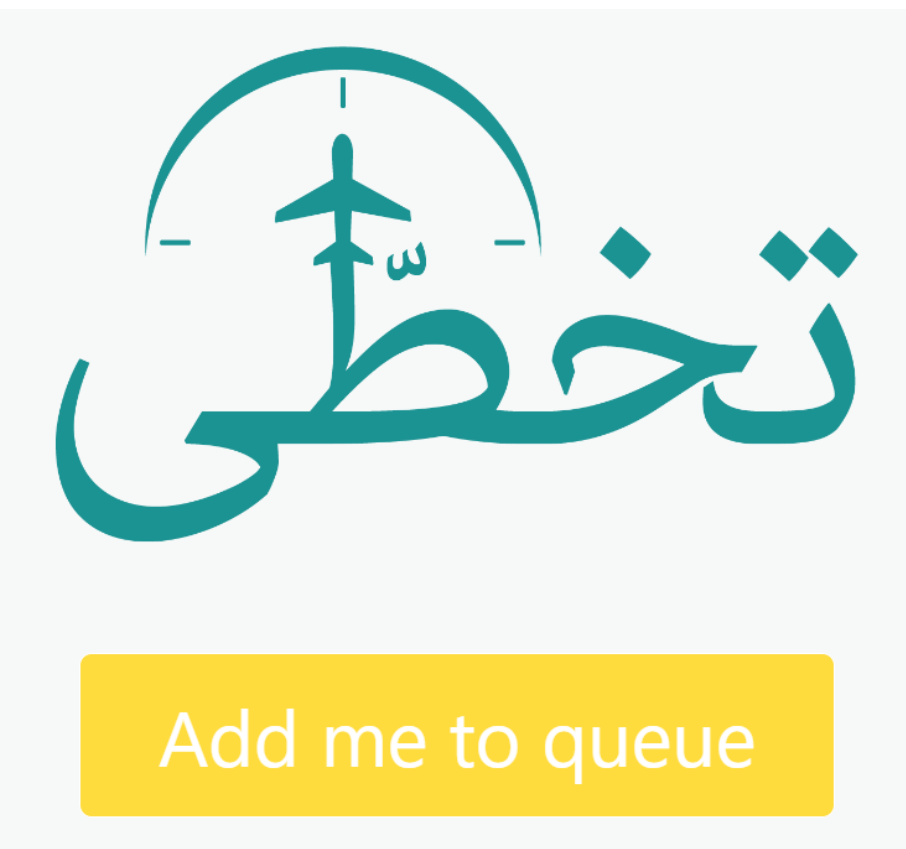

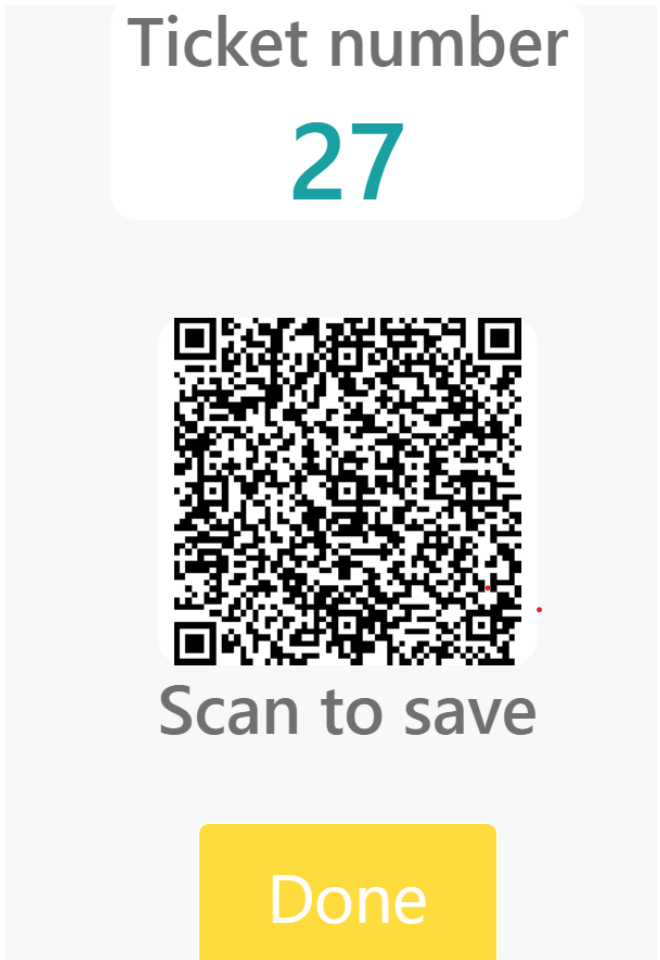

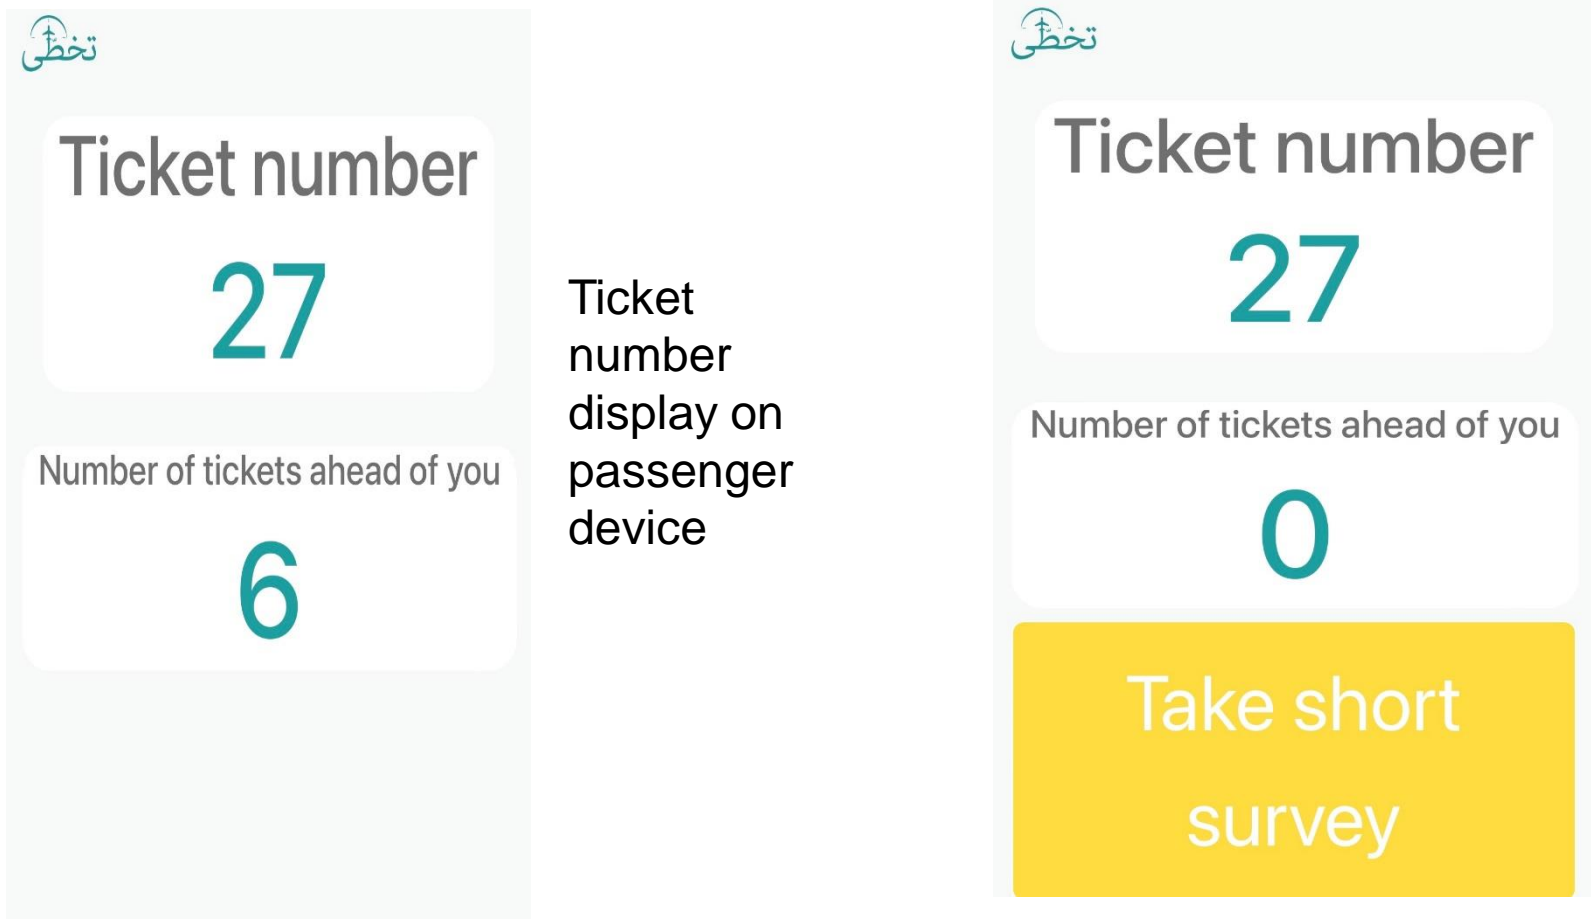

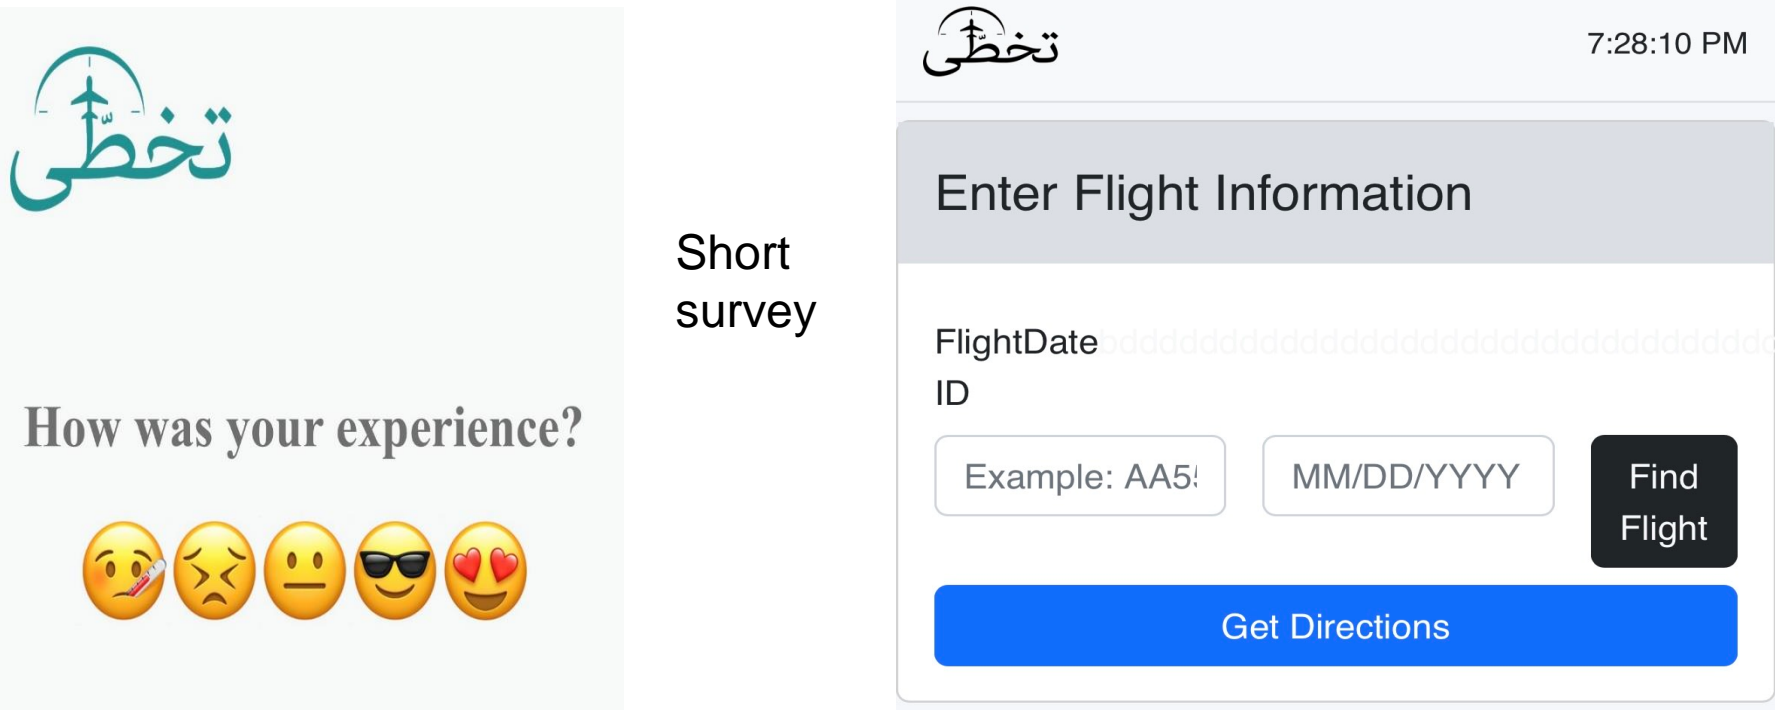

Hasan Ali Hasan Marhoon

Company mentor: Maram AIEskafi  
Supervised by: Adeeb Hamdoon

The virtual queueing system enables BAC to measure the overall success of the system while enabling passengers to enjoy airport facilities, making it vital for the success of Takhatta.

Introduction	Objectives	Technologies
<p>BAC (Bahrain Airport Company) is looking to remove the unnecessary cost of having too many check-in employees on duty as well as not having enough employees to handle high passenger traffic.</p> <p>Staff managers want to create a monthly schedule for employees depending on the departing flights.</p> <p>BAC aims to increase passenger satisfaction prior to the check-in process and enable passengers to enjoy the airport facilities without stressing about the queue.</p>	<p>Business objectives:</p> <ul style="list-style-type: none"><li>Effective allocation of resources</li><li>Reduce passenger queue time</li><li>Increase passenger satisfaction (80-90%)</li></ul> <p>client requirements:</p> <ul style="list-style-type: none"><li>Suitable assignment of check-in employees</li><li>Three-minute queue time</li><li>Record passenger feedback</li></ul> <p>Features:</p> <ul style="list-style-type: none"><li>Virtual queueing system</li><li>Simulation-based predictions</li><li>Manager/check-in employee/passenger dashboards</li><li>Visual representation of predictions/metrics</li></ul>	<div><p>AWS Lambda – Handle backend functionality</p></div> <div><p>AWS DynamoDB – NoSQL database to store data</p></div> <div><p>AWS SNS Send email/SMS notifications</p></div> <div><p>AWS SQS – Handle queueing using FIFO</p></div> <div><p>AWS S3 – Static hosting of webpages</p></div> <div><p>AWS Cognito – User authentication</p></div> <div><p>API Gateway– Rest and WebSocket APIs to connect frontend to backend</p></div> <div><p>AWS IAM – Handle service permissions</p></div> <div><p>Draw.io– Design system architecture</p></div>

Design – virtual queueing system	Employability skills
<p>Virtual queue subsystem architecture:</p> <ul style="list-style-type: none"><li>Places passenger in SQS (queue)</li><li>Records actual wait time for each passenger</li><li>Sends data to three databases</li><li>Notifies management on high passenger traffic</li><li>Redirects to satisfaction survey</li></ul> 	<p>Planning &amp; organizing:</p> <p>The project was very challenging as I wasn’t familiar with the AWS services and don’t have sufficient experience with python. To overcome these challenges, I</p> <ul style="list-style-type: none"><li>Dedicated 25 hours a week to familiarize myself with the console/python</li><li>Regularly asked for feedback from peers/consultant</li><li>Created and stuck to a schedule for all subtasks</li><li>Consistently communicated with team members</li></ul>

Implementation – virtual queueing system	Conclusion
<div><p>On-premise tablet:</p><p>Home screen</p><p>Ticket number 27</p><p>Scan to save</p><p>Done</p><p>Ticket display screen – Dynamically generated QR code for each ticket</p></div> <div><p>Passenger’s personal device:</p><p>Ticket number 27</p><p>Number of tickets ahead of you 6</p><p>Ticket number display on passenger device</p><p>Take short survey</p><p>Short survey</p><p>Passenger flight lookup</p></div>	<p>After thorough testing and meeting with the client for their feedback, the system achieves all the success metrics and all the functional and non-functional requirements have been met.</p> <p>Future work:</p> <ul style="list-style-type: none"><li>Encrypt URL parameters</li><li>Increase idle timeout limit</li></ul>
